Part I

Part 1: Mission-independent formulation

1 General Introduction

There are a lot of different coordinate systems used in the AXAF program, mostly intended for use in constructing and aligning the hardware. This memo is intended to give the ASC SDS group's current understanding of the relationships between them (mirror metrology systems are not yet included) and to define many more systems, which are useful for data analysis of observations both in flight and at XRCF.

1.1 Update notes

1.2 Notational conventions

Each of the pixel coordinate systems is identified by a label beginning with the string ASC, followed by a string identifying the system, and ending with a version number. For example, ASC-CHIP-1.0 (loosely, CHIP coordinates) refers to a pixel system defined by the equation immediately following its bold-face first mention, and satisfying the pixel convention discussed below.

1.2.1 Pixel convention

In all cases where we use discrete pixel numbers, the corresponding real-valued, continuous pixel coordinates are defined to be equal to the pixel number at the center of the pixel. We further recommend that for finite detector planes, one corner be designated as the lower left corner, LL. Then the pixel which has LL as one of its corners (i.e. the lower left pixel) shall be numbered (1,1) so that its center has coordinates (1.0, 1.0). The coordinates of the LL point itself are (0.5, 0.5). If the detector is rectangular with sides of length XMAX, YMAX the pixel coordinates then run from (0.5, 0.5) in the lower left corner (LL) to (XMAX+0.5, YMAX+0.5) in the upper right corner (UR) while the pixel numbers in each axis run from 1 to XMAX, 1 to YMAX.

1.2.2 Vector and coordinate notation

A bold face symbol e.g. $\mathbf{B}$ denotes a point in 3D space. The notation $Y_A(B)$ denotes the Y coordinate of point $\mathbf{B}$ in the 3-dimensional Cartesian coordinate system $A$. When we refer to a point as an argument in this way we usually get lazy and omit the boldface, e.g. $Y_A(B)$. The
notation $P_A(B)$ denotes the triple $(X_A(B), Y_A(B), Z_A(B))$, i.e. the coordinates of $B$ in the $A$ coordinate system. ($P$ is not in boldface since it is not a vector - it is in a specific coordinate system.)

1.2.3 Rotation and translation of Cartesian systems

We define an Euler rotation $\text{Rot}(\phi_E, \theta_E, \psi_E)$ of a Cartesian system $X, Y, Z$ to be the product of three rotations

$$\text{Rot}(\phi_E, \theta_E, \psi_E) = \text{Rot}_1(Z, \psi_E)\text{Rot}_1(Y, \theta_E)\text{Rot}_1(Z, \phi_E)$$  \hspace{1cm} \text{(1)}

where the rotations apply to the successively rotated axes from right to left in the usual sense of matrix multiplication.

The general transformation from a cartesian system $A$ to a system $B$ involves a scaling, a translation, and a rotation. This may be described by seven numbers: the scale factor $K_{AB}$ (choice of units), the position vector $P_B(A0) = (X_B(A0), Y_B(A0), Z_B(A0))$ of the origin of $A$ in the $B$ system, and the three Euler angles $\phi_E, \theta_E, \psi_E$ of the rotation $R(A,B)$ from $A$ to $B$,

$$R(A, B) = \text{Rot}(\phi_E, \theta_E, \psi_E)$$  \hspace{1cm} \text{(2)}

$$R(A, B) = \begin{pmatrix}
\cos \phi_E \cos \theta_E \cos \psi_E - \sin \phi_E \sin \psi_E & \sin \phi_E \cos \theta_E \cos \psi_E + \cos \phi_E \sin \psi_E & -\sin \theta_E \cos \psi_E \\
-\cos \phi_E \cos \theta_E \sin \psi_E - \sin \phi_E \cos \psi_E & \sin \phi_E \cos \theta_E \sin \psi_E + \cos \phi_E \cos \psi_E & \sin \theta_E \sin \psi_E \\
\sin \phi_E \sin \theta_E & -\cos \phi_E \sin \theta_E & \cos \theta_E 
\end{pmatrix}
$$

Then coordinates of a general point $G$

$$P_A(G) = (X_A(G), Y_A(G), Z_A(G))$$  \hspace{1cm} \text{(3)}

may be converted to

$$P_B(G) = (X_B(G), Y_B(G), Z_B(G))$$  \hspace{1cm} \text{(4)}

using the formula

$$P_B(G) = R(A, B)K_{AB}P_A(G) + P_B(A0)$$  \hspace{1cm} \text{(5)}
If
\[ R(A, B) = \text{Rot}(\phi_E, \theta_E, \psi_E) \]  \hspace{1cm} (6)
then
\[ R(B, A) = \text{Rot}(\pi - \psi_E, \theta_E, \pi - \phi_E). \]  \hspace{1cm} (7)
Further, if C is related to B by reflection about the X axis, i.e. \( Y_C = -Y_B, Z_C = -Z_B \) then
\[ R(A, C) = \text{Rot}(\phi_E, \pi + \theta_E, \pi - \psi_E). \]  \hspace{1cm} (8)

1.2.4 Spherical polar coordinates

We also use spherical polar coordinate systems. The WCS paradigm describes general rotations of a spherical polar coordinate system. We define the native cartesian axes \( X,Y,Z \) of a spherical polar system \( (r, \theta, \phi) \) by the equation
\[ (X, Y, Z) = rS(\theta, \phi) = (r \cos \phi \sin \theta, r \sin \phi \sin \theta, r \cos \theta) \]  \hspace{1cm} (9)
so that the north pole is through the positive Z axis and the azimuth is zero along the positive X axis and 90 degrees along the positive Y axis. Any other choice of spherical coordinates \( (r, \theta', \phi') \) may be defined by specifying the Euler rotation matrix which rotates the corresponding native systems into each other.

In the appendix I derive
\[
\begin{align*}
\theta' &= \cos^{-1}(\cos \theta_E \cos \theta + \sin \theta_E \sin \theta \cos(\phi - \phi_E)) \\
\phi' &= \arg(\cos \theta_E \sin \theta \cos(\phi - \phi_E) - \sin \theta_E \cos \theta, \sin \theta \sin(\phi - \phi_E)) - \psi_E
\end{align*}
\]  \hspace{1cm} (10)

2 Data Analysis Coordinate Systems - Imaging

2.1 General model of the system

We model an observatory consisting of several telescopes. Each telescope has an optical system (loosely, ‘mirror’) which images the sky by converting incoming photon paths to outgoing photon paths in a well determined way, and an instrument compartment. In the instrument compartment is an instrument table on which are mounted several instruments. The instruments are fixed with respect to the instrument table, but the table may move relative to the instrument compartment. Further, the instrument compartment itself may move relative to the optical system (for AXAF, this happens only at calibration). Each instrument consists of one or more fixed ‘chips’ or planar detector surfaces of finite area (we don’t imply by this that they are chips in the semiconductor sense). For AXAF, these chips are all rectangular, although note that the ROSAT PSPC is circular. Finally, each chip is subdivided into rectangular (usually square) ‘detector pixels’, enumerating the
set of distinct locations that can be represented in the instrument telemetry stream. (In the case of CCDs, these correspond to physical CCD pixels, while in microchannel plate detectors they are arbitrarily set by the electronics).

The information available to us, the telemetry position, is two dimensional, but to infer the final two dimensional angular incoming sky direction we must calculate a photon position in three dimensional space. Every time we want to make an image, we use a two dimensional pixel plane (possibly losing information in a third dimension). So the three types of coordinate system we will use are:

- Two dimensional pixel plane
- Two dimensional spherical angular coordinates
- Three dimensional cartesian coordinates.

### 2.2 Data Analysis 1: Telemetry to Tangent Plane

Once instrumental details are removed, we derive the CHIP pixel coordinate system which records a location in a 2-dimensional plane pixel surface. The FP (Focal Plane) pixel coordinate system (called DETX,DETY in the FITS files) gives the locations in a pixelized tangent plane to the telescope optical axis. The SKY (X,Y) pixel coordinate system gives locations in a pixelized tangent plane to the nominal RA and Dec of observation. Going from CHIP to FP involves taking out 3-D geometry of the chips, position of the instrument on the optical bench, motion of the optical bench, boresights, and plate scale. Going from FP to SKY involves applying the aspect solution. These three pixel coordinate systems, plus the convenience TDET system which combines the CHIP systems for all the components of one detector and systems associated with dispersive gratings, are the systems that users will see in data analysis. The remaining coordinate systems are used internally to make precise the transformations involved in going from CHIP to FP to SKY.

#### 2.2.1 Telemetry to Chip coordinates

The telemetry coordinates of a photon are a collection (n-tuple) of integers. The formats may be very different from instrument to instrument; for instance, the HRC telemetry coordinates consist of two Tap values and six voltages, while the ACIS telemetry coordinates are directly given as pixel numbers. For each instrument, we provide a rule to convert from telemetry coordinates to our standard data analysis chip pixel coordinates which run from 1 to XMAX, 1 to YMAX. They define a logical plane extending from coordinate 0.5 to XMAX+0.5, 0.5 to YMAX+0.5. In other words, the center of pixel number (1,1) is (1.0, 1.0), and its lower left corner is (0.5, 0.5). The logical plane may be larger than the actual set of possibly active pixels. For instance, for a circular detector such as the ROSAT PSPC, we extend this logical chip pixel coordinate plane to be rectangular. This chip pixel coordinate system is labelled as ASC-CIP-1.0.
The corresponding physical coordinate system is a three dimensional Cartesian system called **Chip Physical Coordinates (CPC)**, giving the physical location of a detected photon event on the active area surface. They are fully defined in terms of the chip pixel coordinates when the pixel size $\Delta_p$ and the array size $XMAX \times YMAX$ is given.

$(X_{CPC}, Y_{CPC}, Z_{CPC})$ are defined to have units of mm. The CPC X and Y axes are coincident with the chip X and Y axes, and the Z axis completes a right handed set. The CPC Z coordinate of any point in the chip has a value of 0.0. The X and Y coordinates run from 0.0 to XLEN and YLEN, where $XLEN = XMAX \times \Delta_p$ and $YLEN = YMAX \times \Delta_p$.

Thus if a photon lands at Chip Physical Coordinates $X_{CPC}, Y_{CPC}$ its chip pixel coordinates (ASC-CHIP-1.0) are

$$
CHIPX = \frac{X_{CPC}}{\Delta_p} + 0.5
$$

$$
CHIPY = \frac{Y_{CPC}}{\Delta_p} + 0.5
$$

or

$$
X_{CPC} = (CHIPX - 0.5)\Delta_p
$$

$$
Y_{CPC} = (CHIPY - 0.5)\Delta_p
$$

Note that CHIPX and CHIPY are by definition linear, by which I mean that the mapping to real physical space is linear. Now for ACIS it so happens that the true CCD pixels satisfy this condition sufficiently accurately, but for HRC the readout values may require linearization and removal of discontinuities.

### 2.2.2 Tiled Detector Coordinates

In an instrument with multiple detector planes, the planes may be tilted with respect to each other, or may be separated by a non-integral number of detector pixels, or both (as in ACIS-I). Projecting onto a 2-D plane (e.g. FP coords) will then lose the identity of individual pixels since one true detector pixel will map to a variable number of square pixels on the projected plane. For recording calibration information like bad pixel lists and inspecting the raw image, it is useful to have a single coordinate system covering the whole instrument which retains true detector pixel identity at the expense of relative positional accuracy. For this purpose we introduced the tiled detector coordinate systems (TDET).

$$
\begin{pmatrix}
TDET_X \\
TDET_Y
\end{pmatrix} = \Delta i \begin{pmatrix}
1 & 0 \\
0 & H_i
\end{pmatrix} \begin{pmatrix}
\cos \theta_i & \sin \theta_i \\
-\sin \theta_i & \cos \theta_i
\end{pmatrix} \begin{pmatrix}
CHIPX - 0.5 \\
CHIPY - 0.5
\end{pmatrix} + \begin{pmatrix}
X_{0i} + 0.5 \\
Y_{0i} + 0.5
\end{pmatrix}
$$

(13)

where the values of $H_i$, $\Delta_i$ and $\theta_i$ are different for each chip. $H_i$ gives the handedness of the planar rotation and has values $+1$ or $-1$, $\Delta_i$ gives the sub-pixel resolution factor, and $\theta_i$ gives the rotation angle of the chip axes with respect to the detector coordinate axes.
2.2.3 Local Science Instrument coordinates

Each instrument has an Instrument Origin which is the nominal focal point for the instrument. For telescopes with movable instrument tables, the actual focal point for a particular observation may be different.

To describe the motion of the instrument table, we use three aligned Cartesian coordinate systems.

- The Science Instrument Translation Frame (STF) coordinate system is fixed in the instrument compartment, and is used to describe the changing position of the instrument table. Its origin is at the flight focus and its axes have +X running from the focus toward the telescope aperture, and +Y and +Z forming a right handed set whose orientation matches that of the observatory coordinates. For AXAF, the direction of instrument table motion is along Z.

- The Science Instrument Translation Table (STT) coordinate system is fixed in the moving instrument table, and is used to describe the positions of the instrument origins relative to each other. The position of its origin is mission-dependent, but the axes are parallel to the STF axes.

- The Local Science Instrument (LSI) coordinate system for each instrument is fixed in that instrument, and is identical to the STT frame but with the origin shifted to the instrument origin.

When the instrument table is moved to put the instrument at its nominal focus position, that means that the LSI origin is coincident with the STF origin. Since the axes are also parallel, STF and LSI coordinates become identical. The STF system therefore measures how much the instrument is offset from its nominal focus.

The STF, LSI and STT coordinate systems are defined to use units of mm. To convert from the LSI system to the STT system, one needs to know the STT coordinates of each LSI origin (i.e.
the location of each instrument on the instrument table). To convert to the STF system, one needs to know the instantaneous position of the instrument table, which we describe by giving the STF coordinates of the STT origin $O_{STT}$.

To convert from a position $P_{LSI}$ in LSI coords to $P_{STF}$ in STF coords, one then performs the vector sum:

$$P_{STF} = P_{LSI} + O_{LSI}(STT) + O_{STT}(STF)$$

(14)

adding the STT coordinates of the LSI origin and the STF coordinates of the STT origin. When the instrument is at its nominal focus, these two vectors are equal and opposite.

To convert from CPC coordinates to LSI coordinates, we need to carry out a rotation and translation. Each instrument has one LSI coordinate system, and several chips each with its own CPC system. The information we need for each chip to define the transformation is the LSI coordinates of each of the four corners of the chip plane (actually, only three of the four are required).

A general point on the plane is

$$r = p_0 + X_{CPC}e_X + Y_{CPC}e_Y$$

(15)

where $p_0$ is the origin of CPC coordinates, and $e_X$ and $e_Y$ are the unit vectors along the CPC axes, with $e_Z$ as the unit normal to the plane.

Let us denote the position vectors of the four chip corners as $LL,UL,UR,LR$. Then the unit vectors of the CPC origin and axes in LSI coordinates are

$$p_0 = LL, e_X = LR - LL, e_Y = UL - LL$$

(16)

and

$$e_Z = e_X \land e_Y.$$  

(17)

![Diagram showing the relationship between CHIP, LSI, and STT coordinates.](image)

Figure 3: The relationship between CHIP, LSI and STT coordinates.

We can recast this in a rotational formulation,

$$P_{G}(LSI) = P_{LL}(LSI) + R(CPC,LSI)P_{G}(CPC)$$

(18)

where the matrix is

$$R(CPC,LSI) = \begin{pmatrix} (e_X)_X & (e_Y)_X & (e_Z)_X \\ (e_X)_Y & (e_Y)_Y & (e_Z)_Y \\ (e_X)_Z & (e_Y)_Z & (e_Z)_Z \end{pmatrix}$$

(19)

These unit axis vectors can easily be derived from the corner coordinates.
Figure 4: The instrument compartment (dashed line) may be misaligned with the telescope mirrors. At calibration, this misalignment (highly exaggerated here) may be significant and variable as the mirror is tilted with respect to the instruments. The instrument bench moves with respect to the instrument compartment, as indicated by the arrow.

Figure 5: The relationship between STT and STF coordinates, AXAF example. The instrument (SIM) table has moved so that HRC is at the focus.
2.2.4 Mirror coordinates

We now specialize to a simple optical system which can be modelled to first order as a thin lens with an optical node N from which rays appear to emerge toward a detector. This simple description is fine for the AXAF HRMA, but won't apply directly to the complicated optical path of the AXAF Aspect Camera. The origin of mirror coordinates (labelled here as MNC for Mirror Nodal Coordinates, in previous versions of the document HNC for HRMA Nodal Coordinates) is the nominal optical node of the mirrors. The $+X$ axis goes from the node toward the entrance aperture, and the $Y$ and $Z$ axes complete a right handed system. To first order, an incoming ray with MNC direction cosines $(-X_N, Y_N, Z_N)$ emerges from the mirror with direction cosines $(-X_N, -Y_N, -Z_N)$. (We use the subscript 'N' for mirror nodal coordinates).

The mirror has a nominal focal length $f$, and a nominal focus at mirror coordinates $(-f, 0, 0)$. We define Focus Coordinates (FC-1.0) as a cartesian system identical to MNC coordinates but with its origin at the focus. Thus

\[ P(MNC) = (-f, 0, 0) + P(FC) \]  \hspace{1cm} (20)

The nominal connection between FC and STF coordinates is

\[ P(FC) = P(STF) \]  \hspace{1cm} (21)

However, we support the more general alignment

\[ P(FC) = O_{STF}(FC) + R(STF, FC)P(STF). \]  \hspace{1cm} (22)

This equation allows us to handle the inversion of the HRMA with respect to the instrument compartment that was originally planned for XRCF.

Associated with the MNC system are two spherical coordinate systems. Mirror Spherical Coordinates measure the off axis angle and azimuth of an incoming ray, and their pole is the MNC $+X_N$ axis. Focal Surface Coordinates measure the off axis angle and azimuth of an emerging ray, with pole at the $-X_N$ axis (toward the focus). Each of these spherical coordinate systems has an associated family of pixel plane coordinate systems (parameterized by the selected pixel size), tangent to the pole of the sphere.

The generic Focal Plane Pixel coordinates are

\[ FPX = FPX_0 + t_x \Delta_x^{-1}(Y_N/|X_N|) \]  \hspace{1cm} (23)
\[ FPY = FPY_0 + t_y \Delta_y^{-1}(Z_N/|X_N|) \]

where $t_x$, $t_y$ are sign parameters which control the orientation of the image. $\Delta_x$ is the pixel size in radians. The actual physical pixel size at the focus, for focal length $f$, is

\[ \Delta_p = f \Delta_x \]  \hspace{1cm} (24)
Figure 6: The Tangent Plane Coordinate system describes the incoming rays, while the Focal Plane Coordinates system describes the angular position of rays emerging from the mirrors. The rays then intersect one of several inclined detector planes, causing events whose locations are described in tiled detector coordinates.

A focal plane pixel coordinate system is defined in terms of this physical pixel size. The nominal focal length of the mirror is then needed to convert to actual angular size. (In practice, the angular size may be directly encoded in a WCS CDELT header parameter).

The Tangent Plane pixel coordinates are defined in the same way, but form the pixel plane for the Mirror Spherical Coordinates. Specifically, we define the standard **ASC-FP-FSC-1.0** variant of focal plane coordinates as \( t_x = 1, t_y = -1 \)

\[
\begin{align*}
FPX &= FPX0 + \Delta^{-1}_x (Y_N/|X_N|) \\
FPY &= FPY0 - \Delta^{-1}_x (Z_N/|X_N|)
\end{align*}
\] (25)

Note that in the focal plane \( X_N \) is negative but we take the absolute value in the formula. The sign on \( FPY \) is then chosen to take out the mirror inversion of the image caused by the optics. The sign on \( FPX \) reflects the fact that we want celestial longitude to increase from right to left when the roll angle is zero.

To repeat this in another way: (assuming zero roll angle and the default chip orientation)

- Source moves to higher RA
- Source moves to left in sky image, so sky \( X \) decreases
- \( FPX \) decreases
- Incoming photon moves to smaller MNC \( Y \) and MNC \( Y/|X| \)
- Image moves to larger MNC \( Y \), FC \( Y \), LSI \( Y \), CHIP \( X \)

and
• Source moves to higher Dec
• Source moves up in sky image, so sky Y increases
• FPY increases
• Incoming photon moves to larger MNC Z
• Image moves to smaller MNC Z, FC Z, LSI Z, CHIP Y

We define the standard ASC-TP-MSC-1.0 version of tangent plane coordinates as

\[ TPX = FPX0 + \Delta_\phi^{-1}(Y_N/|X_N|) \]
\[ TPY = FPY0 - \Delta_\phi^{-1}(Z_N/|X_N|) \]  \hspace{1cm} (26)

(identical to the focal plane coordinates) where here the \((X_N, Y_N, Z_N)\) are the unit vector in MNC coordinates of the incoming ray. Tangent plane coordinates are defined to apply to positions on the 'sky' side of the mirror, and do not include mirror optical distortions, while focal plane coordinates do. In practice we assume that tangent plane and focal plane coordinates are identical, and mirror distortions are handled in the spatial variation of the centroid of the PSF.

Thus in our simple mirror model where an incoming photon coming from unit vector \((X, Y, Z)\) with ray unit vector \((-X, -Y, -Z)\) is imaged to a ray with the same unit vector \((-X, -Y, -Z)\), the tangent plane coordinates of the incoming photon TPX, TPY are equal to the focal plane coordinates of the imaged ray. For incoming rays the sign of X is always negative, so -X is positive.

**For XRCF, we adopt a different convention.** Instead of looking at the sky from the detector, we look at the detector from the source, choosing \(t_x = t_y = -1\). Then FPX is parallel to - MNC Y or + XRCF Y; FPY is parallel to - MNC Z or + XRCF Z. Users should be aware of the difference between FP coordinates at XRCF and in flight.

**Table 1: Default axis orientations**

<table>
<thead>
<tr>
<th>Flight</th>
<th>XRCF</th>

<td>-CHIP X, -CHIP Y</td>
</tr>
</tbody>
</table>

We define Mirror Spherical Coordinates \((r, \theta_H, \phi_H)\) in terms of mirror nodal Cartesian coordi-
Figure 7: The different pixel plane coordinate systems. Distorting effects are highly exaggerated.

nates as follows:

\[
\begin{pmatrix}
X_N \\
Y_N \\
Z_N
\end{pmatrix} = \begin{pmatrix}
r \cos \theta_H \\
r \sin \theta_H \cos \phi_H \\
r \sin \theta_H \sin \phi_H
\end{pmatrix}
\]  

(27)

The angle $\theta_H$ is the MSC off-axis angle and $\phi_H$ is the MSC Azimuth. The inverse is

\[
r = \sqrt{X_N^2 + Y_N^2 + Z_N^2}
\]

\[
\theta_H = \cos^{-1}(X_N/r)
\]

\[
\phi_H = \arg(Y_N, Z_N)
\]

(28)

The Focal Surface Coordinates $(r_F, \theta_F, \phi_F)$ are

\[
\begin{pmatrix}
X_N \\
Y_N \\
Z_N
\end{pmatrix} = \begin{pmatrix}
-r \cos \theta_F \\
r \sin \theta_F \cos \phi_F \\
r \sin \theta_F \sin \phi_F
\end{pmatrix}
\]  

(29)

The angle $\theta_F$ is the FSC off-axis angle and the angle $\phi_F$ is the FSC azimuth. They are related to the MSC coordinates by

\[
\theta_F = \pi - \theta_H, \quad \phi_F = \phi_H
\]

(30)
Figure 8: Imaging the sky in LSI coordinates

The inverse is

\[
\begin{align*}
    r &= \sqrt{X_N^2 + Y_N^2 + Z_N^2} \\
    \theta_H &= \cos^{-1}(-X_N/r) \\
    \phi_H &= \text{arg}(Y_N, Z_N)
\end{align*}
\]
2.2.5 Pixel planes for intermediate systems

We may want to make pixel images for data in coordinate systems such as LSI and STF frames. To do this we use the FP system and set the LSI or STF origin at the nominal focus by specifying a physical pixel size. ASC-FP-STF-1.0 coordinates are like ASC-FP-FSC-1.0 coordinates but ignore the possibility of defocus or misalignment (or dither) between the instrument compartment and the mirrors. ASC-FP-LSI-1.0 coordinates further ignore the possibility that the instrument is not at its standard position in the focus (no SI instrument table correction) while ASC-FP-STT-1.0 coordinates artificially place the STT origin at the focus. For each of these systems,

\[
FPX = FPX0 + \Delta_{sp}^{-1}Y \\
FPY = FPY0 - \Delta_{sp}^{-1}Z
\]  

(32)

where \(\Delta_{sp}\) is the physical pixel size and \(Y,Z\) are the LSI, STT, etc., coordinates, while the X-coordinate is ignored.

The ASC-FP-STF-1.0 pixel coordinate system is also called 'dithered focal plane coordinates' since it can be used to debug XRCF dither mode.

2.3 Data Analysis 2: Tangent Plane to Sky

2.3.1 Sky Pixel Coordinates

The Sky Pixel coordinate system is a translation and rotation of the Tangent Plane pixel coordinate system to align the image with a nominal pointing direction and spacecraft roll angle. For small aspect corrections, sky pixel coordinates (ASC-SKY-1.0) are

\[
X = FPX0 + (TPX - FPX0)\cos\gamma - (TPY - FPY0)\sin\gamma + AX \\
Y = FPY0 + (TPX - FPX0)\sin\gamma + (TPY - FPY0)\cos\gamma + AY
\]  

(33)

The quantities \(AX\) and \(AY\) are the sky frame aspect offsets in pixels, determining the sky pixel coordinates of the optical axis. (Note that the aspect offsets for Einstein and Rosat were stored as detector frame offsets, which required applying the roll angle to; it's not clear to me why this choice was made.)

In general when combining data over a wide range of pointing directions, (mosaicing images) we must reproject to the nominal sky tangent plane.

2.3.2 Physical Tangent Plane coordinates

If the Tangent Plane pixel coordinates represent a position on the tangent plane to the unit sphere at the optical axis, the Physical Tangent Plane coordinate system

\[
\begin{pmatrix}
X_{PTP} \\
Y_{PTP} \\
Z_{PTP}
\end{pmatrix} = \begin{pmatrix}
-\Delta_s(TPX - TPX0) \\
\Delta_s(TPY - TPY0) \\
1
\end{pmatrix}
\]  

(34)
represents the 3D vector from the center of the unit sphere to that position on the tangent plane, which the convention that the $X_{PTP}$ and $Y_{PTP}$ axes run in the direction of increasing RA and Dec respectively in the on-orbit case with zero roll. The PTP system is closely related to HRMA Nodal coordinates. If the direction of the incoming ray is $(X_N, Y_N, Z_N)$ then

$$
\begin{pmatrix}
X_{PTP} \\
Y_{PTP} \\
Z_{PTP}
\end{pmatrix}
= 
\begin{pmatrix}
Y_N/X_N \\
Z_N/X_N \\
1
\end{pmatrix}
$$

(35)

### 2.3.3 Physical Sky Plane coordinates

The Physical Sky Plane coordinate system for zero aspect offset and finite roll angle is

$$
\begin{pmatrix}
X_{PSP} \\
Y_{PSP} \\
Z_{PSP}
\end{pmatrix}
= 
\begin{pmatrix}
X_{PTP} \cos \gamma + Y_{PTP} \sin \gamma \\
X_{PTP} \sin \gamma - Y_{PTP} \cos \gamma \\
Z_{PTP}
\end{pmatrix}
$$

(36)

where $\gamma$ is the spacecraft roll angle.

The PTP and PSP systems are important as you need them to calculate the RA and Dec. However they are only used in internal calculations.

### 2.3.4 J2000 Celestial Coordinates

One can go from Tangent Plane Physical coordinates to J2000 celestial coordinates using the instantaneous pointing direction $(\alpha_A, \delta_A)$. and roll angle $\gamma_A$.

$$
S(\alpha, \delta) = \text{Rot}(\pi/2 + \gamma_A, \pi/2 - \delta_A, \pi - \alpha_A) \begin{pmatrix}
X_{PTP} \\
Y_{PTP} \\
Z_{PTP}
\end{pmatrix}
$$

(37)

Use the nominal pointing direction $(\alpha_0, \delta_0)$ and set the roll angle to zero if using Sky Plane Physical Coordinates:

$$
S(\alpha, \delta) = \text{Rot}(\pi/2, \pi/2 - \delta_0, \pi - \alpha_0) \begin{pmatrix}
X_{PSP} \\
Y_{PSP} \\
Z_{PSP}
\end{pmatrix}
$$

(38)

From TP pixel coordinates, recall that

$$
\begin{pmatrix}
X_{PTP} \\
Y_{PTP} \\
Z_{PTP}
\end{pmatrix}
= 
\begin{pmatrix}
-\Delta_s(TPX - TPX0) \\
\Delta_s(TPY - TPY0) \\
1
\end{pmatrix}
$$

Figure 9: Coordinate systems used in data analysis, 1: Imaging data analysis.

2.4 Simulation: Sky to Telemetry

2.4.1 Mirror Spherical Coordinates to Focal Surface Coordinates

Incoming photons with given mirror spherical coordinates (off axis angle and azimuth) can be described by their tangent plane pixel coordinates. To first order, these are the same as the focal plane pixel coordinates; determining the higher order corrections is the job of ray trace simulators such as SAOSAC. When simulating, we often will not bother with these tangent and pixel plane coordinates but instead will work directly with mirror nodal coordinates.

2.4.2 Focal Surface or Mirror Nodal Coordinates to CPC coordinates

We then have the problem: how to transform from mirror nodal coordinates of a ray emerging from the mirror to the detected photon position. This is harder than working in the data analysis direction. We choose a Cartesian coordinate system (usually LSI coordinates) and calculate the intersection of the ray line with each detector plane. There should be only one detector plane which has an intersection within its finite bounds (i.e., the photon will only hit one of the chips). For
detectors which do not include any tilted or out-of-plane chips (pre-AXAF missions), the calculation is much easier as you can just find the LSI coordinates of the ray when it hits the focal plane.

In our more complicated situation, as before a general point on one of the detector planes is

\[ r = p_0 + X_{CPC} e_X + Y_{CPC} e_Y \]  \hspace{1cm} (40)

where \( p_0 \) is the origin of CPC coordinates, and \( e_X \) and \( e_Y \) are the unit vectors along the CPC axes, with \( e_Z \) as the unit normal to the plane.

The general ray is

\[ r = l_0 + \lambda l \]  \hspace{1cm} (41)

where \( l_0 \) is an arbitrary point on the ray (the output of ray trace or else for approximate calculations, the mirror node), \( l \) is the ray direction, and \( \lambda \) labels positions along the ray. The intersection with the plane is then at

\[ r = l_0 + \frac{(p_0 - l_0) \cdot e_Z}{l \cdot e_Z} l \]  \hspace{1cm} (42)

and we find CPC X and Y by taking the dot product with the CPC unit vectors,

\[ X_{CPC} = r \cdot e_X, \quad Y_{CPC} = r \cdot e_Y \]  \hspace{1cm} (43)
2.4.3 Chip coordinates

We can then recover chip coordinates and telemetry coordinates using the equations from previous sections.

\[
CHIPX = \frac{X_{CPC}}{\Delta_p} + 0.5 \\
CHIPY = \frac{Y_{CPC}}{\Delta_p} + 0.5
\]  

(44)

2.5 Summary of coordinate systems

Each of the physical coordinate systems, representing either a 3-D position or a 2-D angular position, has a corresponding 2-D pixel coordinate system used for display purposes and for practical storage in cases where the third dimension is redundant.

In the following table, I give each physical system with the corresponding pixel plane systems. ‘Label’ is the generic label used to identify the system; data associated with this label is deemed to satisfy the equations in this document, and revisions to the equations will imply version number changes in the label. To isolate a specific system, extra parameters such as the chip ID are required. The table also notes whether information is lost going from the physical to the pixel system.

</table>

The TDET parameters for tiled detector coordinates are arbitrary, so there can be several parallel TDET systems for one instrument and individual TDET labels assigned for each system must be used.
The pixel size used in the FP and TP systems is often equal to the detector pixel size in the nominal focal plane, but sometimes is picked arbitrarily.

2.6 Data Analysis 3: Full treatment with misalignments

The discussion of transforming STF to MNC coordinates above is incomplete. For the full treatment, we consider misalignment of the telescope and optical bench, and include a background spacecraft (or lab) coordinate frame. For instance, at Chandra calibration the background coordinate frame is the XRCF system.

We define the following new frames:

- SC, the spacecraft frame (the XRCF frame plays this role in calibration)
- DFC, the frame along whose axes the STF frame (the science instrument module) is mechanically displaced and rotated.
- MFC, the mirror fiducial coordinate system along whose axes the mirror is commanded to move.

Then a point in STF coordinates can be converted to spacecraft coords by

\[ P(DFC) = O_{STF}(DFC) + R(DFC, STF)P(STF) \]

and

\[ P(SC) = O_{DFC}(SC) + R(SC, DFC)P(DFC) \]

Here \( O_{DFC}(SC) \) is the position in spacecraft coords of the home position of the SIM assembly \( O_{STF}(DFC) \) is the displacement of the SIM assembly relative to this home position, and \( R(DFC, STF) \) is the rotation of the assembly relative to its home orientation. \( R(SC, DFC) \) gives the misalignment of the spacecraft and DFC frames. We further allow an independent motion of the mirror relative to the spacecraft frame.

\[ P(SC) = O_{MFC}(SC) + R(SC, MFC)P(MFC) \]

and

\[ P(MFC) = O_{MNC}(MFC) + R(MFC, MNC)P(MNC) \]

Here \( O_{MFC}(SC) \) is the position of the center of rotation of the telescope in spacecraft coordinates, \( R(SC, MFC) \) give the misalignment of the zero of pitch and yaw relative to the SC system, and \( R(MFC, MNC) \) gives the orientation of the mirrors. \( O_{MNC}(MFC) \) allows for a translation of the mirror node relative to the center of rotation.

For the specific case of Chandra we have:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Name</th>
<th>Flight</th>
<th>XRCF</th>
</tr>
</thead>
</table>

20
The FITS keywords STG.X,Y,Z give the SIM frame displacement, as distinct from SIM.X,Y,Z which give the SIM table position relative to the SIM frame.

3 Data Analysis Coordinate Systems - Gratings

We now consider objective transmission gratings placed between the mirrors and the detectors.

3.1 Data Analysis: Grating data

When we observe with the gratings, we get a dispersed spectrum with orders \( +1, -1, +2, -2, \ldots \) and a zero-order undispersed image. The undispersed (zero-order) photons do not interact with the gratings and we can deal with them using the same analysis as for imaging detectors. To analyse a dispersed photon, however, we must know the location of the zero-order image as well as that of the dispersed photon. For instance, spacecraft roll aspect must be applied to the zero-order position, not the dispersed position.

The location of the zero order photon must be calculated relative to the Grating Node rather than the Mirror Node. The Grating Node is on the optical axis at a distance \( R \) from the focus, where \( R \) is the diameter of the Rowland Circle.

Each grating is defined by a grating node position and a grating pole vector which defines the cross-dispersion direction.

3.1.1 Grating Zero Order Coordinates (GZO-1.0)

Now we pick a source, with zero order position \( ZO \), and let the vector from the grating node to the source zero order be \( S \). Then define

\[
\begin{align*}
e_{x_{ZO}} &= -S/|S| \\
e_{y_{ZO}} &= d_0 \wedge e_{x_{ZO}}/|d_0 \wedge e_{x_{ZO}}| \\
e_{z_{ZO}} &= e_{x_{ZO}} \wedge e_{y_{ZO}}
\end{align*}
\] (45)

where the Grating Pole (cross-dispersion unit vector) \( d_0 \) is

\[
d_0 = (0, -\sin \alpha_G, \cos \alpha_G)
\] (46)
in MNC coordinates, where $\alpha_G$ is the angle between the dispersion direction and the spacecraft Y axis.

This defines a cartesian orthonormal set, Grating Zero Order Coordinates, whose origin we choose to be at $G_0$. Diffracted photons travel in the $X_{ZO}, Y_{ZO}$ plane, and the intersection of this plane with the detector surface defines the dispersion direction.

![Figure 11: Grating Zero Order coordinates](image)

The key step is calculating the GZO to FC transformation matrix. The columns of this matrix are simply the vectors $e_{x_{ZO}}$ etc.

The GZO coordinates of the photon are then

$$P(GZO) = R(FC, GZO)(P(FC) - O_{GZO}(FC))$$  \hspace{1cm} (47)$$

where $O_{GZO}(LSI)$ are the FC coordinates of the grating node.

For an approximate treatment (which can be in error by several pixels), we can write the zero order coords as

$$ZO(FC) = (X, Y, Z) = (gX_o, gY_o, gZ_o)$$  \hspace{1cm} (48)$$

where $g$ is the distance from $G_0$ to the focus. Then to first order

$$|S| = g(1 - X_o)$$  \hspace{1cm} (49)$$

and

$$e_{x_{ZO}} = (1, -Y_o, -Z_o)$$
$$e_{y_{ZO}} = ((Z_o \sin \alpha_G + Y_o \cos \alpha_G), \cos \alpha_G, \sin \alpha_G)$$  \hspace{1cm} (50)$$
$$e_{z_{ZO}} = (-Y_o \sin \alpha_G + Z_o \cos \alpha_G, -\sin \alpha_G, \cos \alpha_G)$$

so that a point with FC coords $(x, y, z)$ will have GZO coords

$$P(GZO) = (x - g, (y - Y) \cos \alpha_G + (z - Z) \sin \alpha_G, (z - Z) \cos \alpha_G - (y - Y) \sin \alpha_G)$$  \hspace{1cm} (51)$$
3.1.2 Grating Angular Coordinates (GAC-1.0)

Grating Angular Coordinates (GAC) are the most important system for grating analysis. The GAC system \((\theta_r, \theta_d)\) is a 2D angular system giving longitude and latitude with respect to GZO coordinates. The longitude coordinate, \(\theta_r\), is the dispersion angle and the latitude coordinate, \(\theta_d\), is the cross-dispersion angle. They are defined as

\[
\begin{align*}
\theta_r &= \tan^{-1}\left(\frac{-Y_{ZO}}{X_{ZO}}\right) \sim -Y_{ZO}/X_{ZO} \\
\theta_d &= \tan^{-1}\left(\frac{+Z_{ZO}}{\sqrt{X_{ZO}^2+Y_{ZO}^2}}\right) \sim +Z_{ZO}/X_{ZO}
\end{align*}
\]  \(52\)

3.1.3 Grating Diffraction Coordinates (GDC-1.0)

The Grating Diffraction Coordinate system \((r_{TG}, d_{TG})\) gives the distance in mm along the dispersion direction and in the cross-dispersion direction. This is just related to the GAC coordinates by a simple scaling

\[
\begin{align*}
r_{TG} &= X_R \theta_r \\
d_{TG} &= X_R \tan \theta_d
\end{align*}
\]  \(53\)

Here \(X_R\) is the length from the grating node to the focus, which is approximately equal to the length \(|S|\).

![Grating Diffraction coordinates](image)

Figure 12: Grating Diffraction coordinates

3.1.4 Grating Diffraction Plane Pixel Coordinates (GDP-1.1)

The Grating Diffraction Plane Pixel Coordinates \(GDX, GDY\) are defined by

\[
\begin{align*}
GDX &= GDX0 - \Delta_g^{-1}(Y_{ZO}/X_{ZO}) \\
GDY &= GDY0 + \Delta_g^{+1}(Z_{ZO}/X_{ZO})
\end{align*}
\]  \(54\)

analogously to the Focal Plane Pixel Coordinates.

They are related to the physical Grating Diffraction Coordinates by

\[
\begin{align*}
GDX &= GDX0 + \Delta_g^{-1}\tan(r_{TG}/X_R) \\
GDY &= GDY0 + \Delta_g^{+1}(d_{TG}/X_R)\cos(r_{TG}/X_R)
\end{align*}
\]  \(55\)
3.1.5 Dispersion relation

The wavelength of the diffracted photon is

\[ \lambda = P \sin \theta_R/m \]  \hspace{1cm} (56)

where P is the average grating period and m is the diffraction order. So

\[ \lambda \sim (P/m)(GDX - GDX0) \Delta g_s \]  \hspace{1cm} (57)

Part II

Part 2: AXAF systems

4 ACIS

4.1 Instrumental details

The ACIS instrument has 10 CCD chips. In the event list data, each is identified by an integer from 0 to 9. Four of the chips, the imaging set, are arranged in a rough square (but individually tilted). Six are the spectroscopic array, arranged in a line.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The CHIP ID is also called CCD ID for consistency with ASCA.

4.1.1 ACIS readout coordinates

The ACIS readout coordinate system was explained in a 1995 draft memo from J Woo. This memo defines two coordinate systems, the “pixel coordinate system of the readout file array, f(x,y)”, which
I will call the ACIS Readout Coordinates \((XREAD, YREAD)\) with identifier AXAF-ACIS-3.0, and the "pixel coordinate system of the active detector image array \(p(x,y)\)”, which I will call ACIS Chip Coordinates, \((XCHIP, YCHIP)\) with identifier AXAF-ACIS-1.0 (these are the ones that run from 1 to 1024).

ACIS Readout Coordinates may be seen in subassembly cal (SAC) data, but in flight the Chip coordinates are calculated on board and telemetered directly. We don’t normally deal with the readout coordinates.

The two systems are related by

\[
YCHIP = \begin{cases} 
YREAD & 1 \leq YREAD \leq 1026 \\
\text{Overclock} & 1027 \leq YREAD \leq 1030 
\end{cases} 
\]  

(58)

\[
XCHIP = \begin{cases} 
XREAD - 4 & 5 \leq XREAD \leq 260 \\
\text{Overclock} & 261 \leq XREAD \leq 337 \\
\text{Undefined Parallel Transfer} & 338 \leq XREAD \leq 340 \\
\text{Underclock} & 341 \leq XREAD \leq 344 \\
857 - XREAD & 345 \leq XREAD \leq 600 \\
\text{Overclock} & 601 \leq XREAD \leq 677 \\
\text{Undefined Parallel Transfer} & 678 \leq XREAD \leq 680 \\
\text{Underclock} & 681 \leq XREAD \leq 694 \\
XREAD - 172 & 685 \leq XREAD \leq 940 \\
\text{Overclock} & 941 \leq XREAD \leq 1017 \\
\text{Undefined Parallel Transfer} & 1018 \leq XREAD \leq 1020 \\
\text{Underclock} & 1021 \leq XREAD \leq 1024 \\
2049 - XREAD & 1025 \leq XREAD \leq 1280 \\
\text{Overclock} & 1281 \leq XREAD \leq 1357 \\
\text{Undefined Parallel Transfer} & 1358 \leq XREAD \leq 1360 
\end{cases} 
\]  

(59)

The inverse transformation is

\[
YREAD = YCHIP \\
XREAD = \begin{cases} 
XCHIP + 4 & 1 \leq XCHIP \leq 256 \\
857 - XCHIP & 257 \leq XCHIP \leq 512 \\
XCHIP + 172 & 513 \leq XCHIP \leq 768 \\
2049 - XCHIP & 769 \leq XCHIP \leq 1024 
\end{cases} 
\]  

(60)

Unresolved questions: Is the above correct, or even useful? Do the telemetry values start at 1 or 0? Under what circumstances do we get YCHIP values of 1025 and 1026? Do those values correspond to true active area?
4.1.2 ACIS Fast Window mode

In window mode, we get an initial set of Window Chip Coordinates (AXAF-ACIS-4.0) WX, WY which run from 1 to 1024 and 1 to WSIZE. WSIZE is a configurable number.

There is no way to uniquely know from the telemetry what the true ACIS chip coordinates of the photon were - you get an uncertainty module WSIZE. However, to calculate best guess ACIS chip coordinates (AXAF-ACIS-1.0) we can assume that the photon is associated with a known incident source location, resolving the uncertainties.

For non grating data, calculate the predicted AXAF-ACIS-1.0 coordinates for the incident radiation, say (CX0, CY0). At XRCF, this will involve the forward calculation including the STF coordinates of the FAM. Then set

\[ CY1 = (CY0 / WSIZE) \ast WSIZE \]

using integer arithmetic. Then

\[ CHIPX = WX \] (61)

and

\[ CHIPY = WY + CY1 \] (62)

4.2 2-D detector coordinates: TDETT parameters

The ASC-TDETF-1.0 tiled detector coordinates are implemented for AXAF with the following specific systems, each of which specifies a TDETF system in terms of the CHIP coordinates.

4.3 3-D chip locations: CPC to LSI transformation parameters

In the following tables we list the CPC and LSI coordinates of each corner of each chip. We give coordinates for each of the ACIS chips in both the ACIS-I and ACIS-S LSI systems, since we may take data from ACIS-S chips while ACIS-I is in the focus or vice versa. The systems are simply
offset by 46.88mm in the $Z_{LSI}$ direction. The ACIS data is from ACIS-SOP-01, and the HRC data is deduced from information provided by M. Juda.

5 HRC

5.1 Overview

The HRC instrument has two detectors, the HRC-S and the HRC-I. The HRC-I has a single 'chip' or segment/microchannel plate pair (CHIP ID = 0, name HRC-I) while the HRC-S has three (CHIP ID = 1,2,3; name HRC-S1,S2,S3; HRC team segment designation +1, 0, -1). We define an HRC-I chip plane which is 16384 pixels square; (not all of these pixels correspond to actual readable values); the HRC-S chips are 4096 x 16456 pixels The pixel size is 0.0064294 mm.

5.1.1 3-D chip locations: CPC to LSI parameters

The corners of these logical chip planes are located in the LSI coordinate system as follows; these are calculated by placing the HRC-S origin (default aimpoint) at 4.0mm to +LSI Y of the overall detector center and using the chip sizes calculated above together with the designed S1 and S3 chip tilts in the X,Y plane. Note that S2 is no longer centered around the detector center, since its edges are determined by the measured gap locations.

5.2 Instrumental details

5.2.1 HRC physical layout and Tap Coordinates (HRC-6.0)

Each HRC sub-instrument contains a series of electrical 'taps' on each axis of the wire grid, which define a continuous spatial system. The electrical axes are labelled \( u \) and \( v \), and we will say there are \( N_u \) and \( N_v \) taps on each axis, numbered starting at 0. In the internal HRC-S electronics the three MCPs have individually numbered taps but these are combined before we see it in the telemetry. The coarse tap positions are modified by a fine position which runs from -0.5 to +0.5. Then we can define an **HRC Tap Coordinate System (AXAF-HRC-6.0)** which runs from \( u = -0.5 \) to \( u = N_u - 0.5 \), and \( v = -0.5 \) to \( N_v - 0.5 \).

5.2.2 Deriving linear tap coordinates from HRC telemetry

The instrument electronics records four numbers per axis for each event: the 'center tap' (usually the tap with the maximum voltage), and the voltages of that tap and the one on either side. These numbers, which are the values which get coded into flight telemetry, we will refer to as **HRC**
telemetry coordinates \((u_{ht}, v_{ht})\). The four integer components of \(u_{ht}\) are

\[
u_{ht} = \begin{cases} 
u_0 & \text{Max tap, 0 to } N_u - 1 \text{ ('coarse position')} \\ 
\text{ADC1} & \text{Voltage of } u_{\text{coarse}} - 1 \\ 
\text{ADC2} & \text{Voltage of } u_{\text{coarse}} \\ 
\text{ADC3} & \text{Voltage of } u_{\text{coarse}} + 1 
\end{cases}
\] (63)

and similarly for \(v_{ht}\). From the telemetry coordinates we can calculate an intermediate quantity, the fine position

\[
u_{\text{fine}} = \frac{\text{ADC3} - \text{ADC1}}{\text{ADC1} + \text{ADC2} + \text{ADC3}}
\] (64)

Note that

\[-0.5 \leq \nu_{\text{fine}} \leq +0.5\] (65)

We now split off the sign of this fine position correction to obtain the tap side

\[
s_u = \begin{cases} 
+1 & (\nu_{\text{fine}} \geq 0) \\
-1 & (\nu_{\text{fine}} < 0) 
\end{cases}
\] (66)

and the fine position magnitude

\[\Delta u = |\nu_{\text{fine}}| \] (67)

From these we calculate the linear HRC Tap Coordinates

\[
\begin{align*}
u &= \nu_0 + s_u \nu_1 (\nu_0, s_v) \Delta u - s_v \nu_{\text{coarse}} (\nu_0, s_v) \Delta u^2 \\
v &= \nu_0 + s_v \nu_1 (\nu_0, s_v) \Delta v - s_v \nu_{\text{coarse}} (\nu_0, s_v) \Delta v^2
\end{align*}
\] (68)

The C factors are called the degapping parameters; for HRC they have different values for each tap and tap side. Earlier detectors (Einstein and Rosat HRI) assumed C factors which were independent of coarse position.

The simplest choice of the degapping parameters is to take

\[
\begin{align*}
\nu_1 &= \nu_{\text{coarse}} = 1 \\
\nu_2 &= \nu_{\text{coarse}} = 0,
\end{align*}
\] (69)

giving us HRC raw tap coordinates,

\[
\begin{align*}
u_{\text{raw}} &= (\nu_{\text{coarse}} + \nu_{\text{fine}}) \\
v_{\text{raw}} &= (v_{\text{coarse}} + v_{\text{fine}})
\end{align*}
\] (70)

These coordinates do not provide a continuous system over the detector, and an HRC image plotted in raw coordinates contains 'gaps'. With some choice of the degapping parameters, we obtain
a continuous (but not linear) system giving an image with no gaps. **HRC degapped coordinates** \((u_{dg}, v_{dg})\). Example values from Murray and Chappell (1989) of \(C\) used to give degapped coordinates are

\[
C_{u1} = C_{v1} = 1.049
\]

\[
C_{u2} = C_{v2} = 0.110,
\]

so

\[
u_{dg} = (u_{\text{coarse}} + 1.049u_{\text{fine}} - 0.11u_{\text{fine}}|u_{\text{fine}}|) \\
v_{dg} = (v_{\text{coarse}} + 1.049v_{\text{fine}} - 0.11v_{\text{fine}}|v_{\text{fine}}|)
\]

The coefficients to be used for the HRC have not yet been determined.

### 5.2.3 HRC Chip Coordinates (HRC-1.1)

The HRC Telemetry Pixel Number System scales the taps by a pixel size \(\Delta_t = 256\) to give

\[
T_{LU} = (u + 0.5) \ast \Delta_t \\
T_{LV} = (v + 0.5) \ast \Delta_t,
\]

integer pixel numbers which start with pixel 0 (for a tap value of -0.5). This definition is corrected from the one in editions 4 and earlier of this memo.

For compatibility with other data archives, we add one to these engineering coordinates and then divide them up into individual chips to get HRC Chip Coordinates (AXAF-HRC-1.1)

\[
CHIP_X = (u - u_0) \ast \Delta_t + 0.5 = T_{LU} - \Delta_t \ast (u_0 + 0.5) + 0.5 \\
CHIP_Y = (v - v_0) \ast \Delta_t + 0.5 = T_{LV} - \Delta_t \ast (v_0 + 0.5) + 0.5
\]

Note that \(u_0 = -0.5\) always. \(v_0 = -0.5\) for HRC-I; +0.5 for HRC-S1; 64.5 for HRC-S2; 126.5 for HRC-S3. This corresponds to HRC-S tap boundaries at 64.5 and 126.5. It returns us to a system in which the taps are numbered separately for each chip.

**Table 12: HRC-S1 TELV, v and CHIPY**

<table>
<thead>
<tr>
<th>TELV</th>
<th>Coarse v, Fine v</th>
<th>CHIPY</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0, -0.5</td>
<td>-255</td>
</tr>
<tr>
<td>16640</td>
<td>64, +0.5</td>
<td>16384</td>
</tr>
</tbody>
</table>

In this system, 1 pixel = 0.0064294 mm = 0.13 arcsec. The size of one tap is 1.646mm. Now this coordinate system actually covers a larger area than the true possible coordinates. For instance,
v taps 0 and 1 for HRC-S1 are missing, so the lowest possible v coordinate in the telemetry for HRC-S is 1.5 (corresponding to tap 2 with fine position -0.5) but even this does not correspond to a valid detected event position. Nevertheless, we will define our logical coordinate system to cover the range of v coordinates starting at CHIPX, CHIPY = 0.5 (lower left corner of first pixel) which corresponds to HRC-S u, v = (-0.5, +0.5). Version 3.0 of this document defined chip coordinate system AXAF-HRC-1.0 which did not cover this full logical range and had a slightly different origin; the current system is denoted AXAF-HRC-1.1.

The center of HRC-S2 is then at \((u, v) = (7.5, 95.5)\) and the gaps between the MCPs are at \(v\) values of 62.96 to 64.12 and 124.88 to 126.04. In earlier work I arbitrarily set the chip boundaries at 63.0 and 126.0 so that each chip has a length of 63.0 taps, but on recommendation from M. Juda I have adjusted the chip sizes so that the true chip gaps fall on the logical chip boundaries.

<table>
<thead>
<tr>
<th>Chip</th>

<td>128.5 to 3968.5</td>
<td>0.5 to 16384.5</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Now let's look at the boundaries on HRC-S and HRC-I more closely. We keep extra figures for self-consistency only assuming a tap scale of 1.6460 exactly, and measure positions starting at the physical position corresponding to chip pixel position 0.5 (bearing in mind this may be outside of the wire grid).
I used the following information on the HRC-S:

Tap size is 1.646 mm (M. Juda)
16384 pixels = 105.344 mm: logical chip size = tap size 1.646 mm x 64 taps
MCP physical size 100.000 mm x 27.000 mm from 'TOP MCP COORDINATES' drawing
Total logical length is 3 x 105.344 mm
Total physical length is 3 x 100.000 mm + 2 x gap size = 1.905 mm.
S2 Center is center of both total logical and total physical length.
Coating extends 94.5mm on outer MCPs and 16mm wide (M. Juda)

Post XRCF revision 1: (M Juda Oct 97)
S1 TELU range from 600 to 3496, TELV from 1190 to 16250 with
CsI limit at 1613.
S2 TELU from 600 to 3488, TELV from 16990 to 32261
S3 TELU from 600 to 3504, TELV from 32925 to 48110 with CsI
limit at 47650.

The coating strip is at TELU = 2660 (S1), 2670 (S2), 2670 (S3)
with the 'T' strip at TELV from 22780 to 27670.

More accurate post XRCF data: MCP edges at TELV = 16428, 17012, 32244, 32932.

This information leads to the following MCP layout:

![MCP Layout](image)

The CPC coordinates run from 0.0 to 26.33 (X_{CPC} for HRC-S) and from 0.0 to 105.3 (Y_{CPC} for HRC-S and both axes for HRC-I).

The active area of each microchannel plane is smaller, and the area coated with photocathode
is smaller still. For HRC-I, the chip is 100 x 100 mm, with a 93 x 93 mm active area and a 90 x 90 mm coated area. For HRC-S, each chip is 100 x 27 mm, the active area is 100 x 20 mm, and the coated area is 94.5 x 16.0 mm. except for HRC-S2 where the coated area is 100 x 16 mm. Using these numbers, we derive the locations of the various areas in CPC (mm) and Chip (pixel) coordinates listed above.
6 The SIM

6.1 Chip orientation summary tables

The following table gives the Euler rotation angles for the chips. The LSI to CPC transformation is more intuitive; the first angle $\phi$ indicates the tilt with respect to the LSI plane (with HRC-I having $\phi = 180$ to indicate being completely flipped over, another way of expressing the different handedness of its axes); and the third angle $\psi$ indicates the rotation of the chip in the LSI Y,Z plane relative to chip I0.

</tr>
</tbody>
</table>
6.3 Aimpoints

Several named default aimpoints are defined for the various AXAF instruments. The table below gives the STF coordinates of the instrument table origin for each of these aimpoints. Most observations will use one of these default aimpoints, but in general the SIM can be moved in X and Z to any aimpoint.

</tbody>
</table>

7 The HRMA (flight)

7.1 HRMA nodal coordinates

The conversion from STF (instrument compartment) to MNC (HRMA nodal) coordinates requires knowledge of the focal length, which is 10061.0 mm.

$$\begin{pmatrix} X_{STF} \\ Y_{STF} \\ Z_{STF} \end{pmatrix} + \begin{pmatrix} f \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} X_N \\ Y_N \\ Z_N \end{pmatrix}$$ (77)

In flight, the orientation of the SIM with respect to the HRMA is fixed. In the flight nominal configuration, one of the SIs has its nominal focal point at the telescope focus. However, the SIM can be moved so that the nominal focal point and the telescope focus do not coincide (general flight configuration).

7.2 Focal and Tangent plane systems

We define the following focal plane pixel systems, together with their usual purpose (although one may still use e.g. FP-2.0 with XRCF ACIS data, etc.). The coordinate systems are defined in terms of their physical pixel size at the nominal flight focal length $f = 10061.0$ mm. The corresponding angular sizes are also given, but the actual angular size will be different for XRCF/HRMA and XRCF/TMA data.

We define systems for the nicely rounded pixel sizes and for the accurate actual pixel sizes. We've decided to use the mean actual pixel sizes for the flight system. Thus, the size of an HRC-I
pixel at the nominal focal distance of 10061.0 mm is 0.132 arcseconds, so 0.132 arcseconds is defined as the FP-2.1 pixel size (even if the detector is moved well off focus). The HRC-S detector has a maximum linear extent of over 48500 pixels. When making sky coordinates for such a detector, we must define a square pixel plane (to allow for the roll angle). We choose a 65536 pixel sided plane, defined as FP-2.3. This plane has a total of 4.3 gigapixels, slightly more than can fit in a 4-byte signed integer. We therefore recommend not making full resolution full frame image files in this coordinate system.

Here are the current flight pixel systems:

<table>

</table>

(The total image size should be $2^*(FPX0-0.5)$).
However, software should also support generic ASC-FP/TP coordinates with arbitrary pixel size
and sign choices.

7.2.1 Mosaicing XRCF images

We want to make mosaiced images which show the point spread function at different off axis angles over the whole field of view. The AXAF-FP-2.0 or -2.1 systems are therefore of interest. However, a single XRCF ACIS-2C image covers only a small part of the field. We don’t want to make a 32768 square image when only a 4096 square part is used. As long as we stay in event list format, there is no storage problem, but in an image we should make only the minimal subset and store the location within the larger image as a WCS. The AXAF-FP-5.1,6.1 systems can be used for this purpose.

7.3 Angular systems

7.3.1 HRMA Left Handed Spherical Coordinates (AXAF-HSC-1.1)

This system is used to express off-axis angles. We define HRMA Spherical Coordinates \((r, \theta_H, \phi_H)\) in terms of HRMA nodal Cartesian coordinates as follows:

\[
\begin{pmatrix}
  X_N \\
  Y_N \\
  Z_N 
\end{pmatrix} = \begin{pmatrix}
  +r \cos \theta_H \\
  -r \sin \theta_H \cos \phi_H \\
  r \sin \theta_H \sin \phi_H 
\end{pmatrix}
\]  

(78)

The inverse is

\[
\begin{align*}
  r &= \sqrt{X_N^2 + Y_N^2 + Z_N^2} \\
  \theta_H &= \cos^{-1}(X_N/r) \\
  \phi_H &= \arg(-Y_N, Z_N)
\end{align*}
\]  

(79)

This coordinate system is also used for input to the XRCF Test Database; it is a LEFT HANDED coordinate system. The XRCF test database immediately converts these to pitch and yaw. The north pole of this system is the center of the forward aperture of the HRMA A0; \(\theta_H\) measures the off-axis angle of the incoming ray and \(\phi_H\) measures its azimuth in the \(Y_N, Z_N\) plane such that for an observer at XRCF standing by the SI and looking at the XSS, \(\phi_H = 0\) is to the left and \(\phi_H = \pi/2\) is vertically downwards.

Then the forward aperture of the HRMA, A0, has HRMA nodal coordinates \((a, 0, 0)\) and HSC coordinates \((a, 0, 0)\). The focal point F of the HRMA has HRMA nodal coordinates \((-f, 0, 0)\) and HSC coordinates \((f, \pi, 0)\).

The HSC-1.1 system actually makes most sense when looking in the sky plane. Consider a source in the sky when roll angle is zero:

- The FPX, FPY and X, Y axes are aligned.
• RA, Dec are parallel to -X, +Y. (since RA increases toward the left looking at the sky).

• The +X, +Y axes are parallel to -SCY, +SCZ. A photon from larger Dec and smaller RA than the field center comes from the +X, +Y direction. It enters the telescope from -SCY, +SCZ, and therefore has HSC coordinate azimuth between +0 and +90 deg. Thus, the HSC azimuth is just the conventional plane polar coordinate angle in the +FPX, +FPY tangent plane coordinate system.

• After passing through the (ideal) mirror origin, the photon leaves from +SCY, -SCZ and lands at +LSI Y, -LSI Z. (The HSC coordinates of the outgoing photon have azimuth between 180 and 270, and off axis angle between 90 and 270, but this is not normally of interest.)

7.3.2 HRMA Right Handed Spherical Coordinates (AXAF-HSC-1.2)

To satisfy my desire for using left handed systems as little as possible, I defined HSC-1.2 to be the same as HSC-1.1 except that the azimuth increases in the opposite direction: \( \phi_{HR} = 0 \) is to the left and \( \phi_{HR} = \pi/2 \) is vertically upwards. This system has not been used and is now deprecated.

\[
\begin{pmatrix}
X_N \\
Y_N \\
Z_N
\end{pmatrix} = \begin{pmatrix}
 r \cos \theta_{HR} \\
 -r \sin \theta_{HR} \cos \phi_{HR} \\
 -r \sin \theta_{HR} \sin \phi_{HR}
\end{pmatrix} \tag{80}
\]

The inverse is

\[
\begin{align*}
r &= \sqrt{X_N^2 + Y_N^2 + Z_N^2} \\
\theta_{HR} &= \cos^{-1}(X_N/r) = \theta_H \\
\phi_{HR} &= \arg(-Y_N, -Z_N) = -\phi_H
\end{align*} \tag{81}
\]

7.3.3 HRMA rotation coordinates (Pitch and Yaw) (AXAF-HSC-3.0)

A third choice of pole is the +Y axis, whose latitude-like coordinates \( \alpha_z \) is called yaw, and whose azimuthal coordinate \( \alpha_y \) is called pitch. The mapping between pitch and yaw coordinates and HRMA coordinates is

\[
\begin{pmatrix}
X_N \\
Y_N \\
Z_N
\end{pmatrix} = \begin{pmatrix}
 +r \cos \alpha_z \cos \alpha_y \\
 +r \sin \alpha_z \\
 -r \cos \alpha_z \sin \alpha_y
\end{pmatrix} \tag{82}
\]

or

\[
\begin{align*}
\alpha_z &= \sin^{-1}(Y_N/r) \\
\alpha_y &= \arg(X_N, -Z_N)
\end{align*} \tag{83}
\]
The rotation matrix from HSC-1.2 right-handed spherical coords is

\[ R(\text{HSC-1.2,HSC-3.0}) = \text{Rot}(\pi, \pi/2, \pi). \] (84)

The motivation for this coordinate system is its relationship to the commanded pitch and yaw of the HRMA at XRCP. We call the pitch and yaw coordinates of the XSS \( \alpha_y(XSS) = \alpha_{y0} \) and \( \alpha_z(XSS) = \alpha_{z0} \). To put the XSS at these coordinates, the HRMA must be yawed \( \alpha_{z0} \) to the left and its aperture pitched \( \alpha_{y0} \) downward.

7.3.4 HRMA Source coordinates \( \text{(AXAF-HSC-2.1)} \)

The HRMA Source Coordinate system \( (r, az, el) \) is a pseudo RA, Dec system that gives the ‘sky’ position of the source as seen by the HRMA. Unlike HRMA spherical coordinates, they have a pole at \(-Z_N\) rather than \(X_N\). The relationship between Source coordinates and HRMA nodal coordinates is:

\[
\begin{pmatrix}
  X_N \\
  Y_N \\
  Z_N
\end{pmatrix} =
\begin{pmatrix}
  +r \cos el \cos az \\
  -r \cos el \sin az \\
  -r \sin el
\end{pmatrix}
\] (85)

Coordinates \( az = 0, el = 0 \) refer to a source on the HRMA axis (center of the field of view); positive \( el \) gives a source above the HRMA axis (top of the field of view), while positive \( az \) gives a source to the left of the center of the field of view. (HSC-2.0 had \( az \) going the other way, creating a left-hand system). The inverse function is

\[
\begin{align*}
el &= \sin^{-1}(-Z_N/r) \\
az &= \arg(X_N, -Y_N)
\end{align*}
\] (86)

The rotation matrices from the other HRMA angular systems are

\[
R(\text{HSC-1.2,HSC-2.1}) = \text{Rot}(\pi/2, \pi/2, \pi); \quad R(\text{HSC-3.0,HSC-2.1}) = \text{Rot}(\pi/2, \pi/2, 3\pi/2).
\] (87)

8 HETG and LETG

The Grating Node is on the optical axis at a distance \( R \) from the focus, where \( R \) is the diameter of the Rowland Circle. The nominal Rowland Circle diameter is quoted as 8650.0 mm [?], Appendix A, p. 11; 8633.69 mm [?], Drawing 301331, Sheet 3; and 8636.00 mm [?]. I will adopt the value from the drawing, i.e. 8633.69mm. (However View F on the same drawing shows the Rowland circle intercepting the X axis at \( X_A = 372.116 \) corresponding to \( R = 8643.11 \text{ mm}. \) This is an error caused by confusing H0 and H1 when measuring the location of the OTG origin.)

The MNC coordinates of the Grating Node \( G0 \) in flight are

45
\[
\begin{pmatrix}
X_N(G0) \\
Y_N(G0) \\
Z_N(G0)
\end{pmatrix} = \begin{pmatrix}
-1431.81 \\
0 \\
0
\end{pmatrix}
\]

(88)

The exact value is different at XRCF. We use the same physical pixel size as for the detector systems, which correspond to somewhat different angular sizes than the imaging case because we are measuring angles from G rather than H0. However, in the case of ACIS, we hope to get extra resolution by using the sub-pixel dither of the detector relative to the sky coordinate zero order position. So, in the GDP-1.1 system we have chosen the GDP pixel size for ACIS and HRC to be the same 6 micron value. (In an earlier version of this memo, the GDP-1.0 system was described with 24 micron ACIS GDP pixel sizes. That system was never implemented.)

What is the extent of the GDP coordinate system? In the case of HRC-S, our worst case is a zero order at an extreme end of the 3-chip array. In that case, you could be as many as 49152 pixels down the dispersion coordinate. This is such a pathological case that we have decided not to build our definitions around it. A normal case would be a zero order in the center, with dispersion coordinates up to plus or minus 25000 pixels or so. As a compromise to support most off axis cases, we adopt pixels running from 1 to 65536 in the dispersion direction, giving 32768 pixels on either side of zero order. In the cross dispersion direction, with HRC-I as the detector, we might have photons up to 16384 pixels from the zero order in principle, and 8192 even if the source is centered in the detector. For ACIS, the extreme range is 32678 super-resolved pixels in the dispersion direction and 24800 pixels in the cross dispersion direction. For both ACIS and HRC, the GDP-1.1 system is sized to be 65536 pixels in the dispersion direction and 32678 pixels in the cross dispersion direction, with the zero order position at (32768.5, 16384.5). However, we recommend that in normal use the 32768 x 4096 subarray extending from (16384,14336) to (49152,18432) be used. This subarray is defined as AXAF-GDP-1.2; it has the same pixel size as GDP-1.1.

9 XRCF

9.1 XRCF coordinates

For much of XRCF, the HRMA sits aligned with the Facility Optical Axis in its 'rest' position, but it can be tilted in two axes. We therefore need to distinguish between facility (XRCF) coordinates and mirror (MNC) coordinates.

In the XRCF, we have the HRMA mounted on two axes - it can change its yaw (azimuth) and pitch (elevation), or equivalently the polar angle and polar azimuth. The instrument (SI) is mounted on either the FAM (Five Axis Mount) or the HXDS (HRMA X-ray Detection System). In the default configuration C0, the HRMA axis and the SI are aligned with the FOA (Facility Optical Axis) and the SI nominal focus S is located at the actual focus F. The X-ray Source System (XSS) is fixed in the XRCF frame and lies on the positive \( X_{XRCF} \) axis (see below).

The origin of XRCF coordinates is at the HRMA CAP (H1).

10 ACIS-2C

The ACIS-2C instrument is used for ground calibration at XRCF. The two chips are similar to the flight ACIS chips, and will frequently be used in Fast Window mode.

</tbody>
</table>

In addition, the raw FAM values must be adjusted by (87.92, 12.94, 7.55) to get FAM coordinates relative to the DFC origin.

11.2 HRMA motion

In the nominal configuration CN, the HRMA is tilted but the SI is moved so that its normal $X_{LSI}$ axis remains coincident with the HRMA optical axis $X_{XRCF}$. In the most general configuration the HRMA and SI are both moved relative to the XRCF but the $X_{LSI}$ axis is not made to coincide with the $X_{XRCF}$ axis.

**WARNING:** The terms 'on-axis' and 'off-axis angle' are correctly used to refer to an angle relative to the optical axis of the HRMA. However, at XRCF they are sometimes used to mean an angle relative to the Facility Optical Axis, which could lead to confusion. I will always use the concept of on and off axis to refer to the HRMA optical axis.
The $Y_{LSI}, Z_{LSI}$ plane contains the science instrument, which returns coordinate values of events measured in detector pixels CHIPX, CHIPY from each of several discrete planar 'chips' (or MCPs in the case of HRC). In data analysis we consider two complementary problems:

- The forward case: Given an XRCF configuration, at which chip CHIP.ID and chip pixel CHIPX, CHIPY will the XSS photons fall? In other words, where do we expect the image to be?

- The inverse case: Given a photon landing on chip CHIP.ID and chip pixel CHIPX, CHIPY, from which direction (off-axis angle and azimuth) did the incoming photon approach the HRMA?

### 11.2.1 XRCF to MNC transformation

We assume that the rotation is around the point $O_{MNC} = (0, 0, 0)$ in MNC coordinates, or $(XH, 0, 0)$ in XRCF coordinates, where $XH = 9.42$.

In terms of the pitch and yaw, the transformation between XRCF and MNC coordinates is given by the translation vector $(X_N(H1), 0, 0) = (XH, 0, 0)$, and the Euler rotation matrix

$$R(XRCF, MNC) = Rot(\alpha_z, \pi + \alpha_y, \pi) \quad (89)$$

or explicitly

$$\begin{align*}
X_N &= (X_{XRCF} - XH) \cos \alpha_z \cos \alpha_y + Y_{XRCF} \sin \alpha_z \cos \alpha_y - Z_{XRCF} \sin \alpha_y \\
Y_N &= (X_{XRCF} - XH) \sin \alpha_z + Y_{XRCF} \cos \alpha_z \\
Z_N &= -(X_{XRCF} - XH) \cos \alpha_z \sin \alpha_y - Y_{XRCF} \sin \alpha_z \sin \alpha_y - Z_{XRCF} \cos \alpha_y
\end{align*} \quad (90)$$

and the inverse

$$\begin{align*}
X_{XRCF} &= XH + X_N \cos \alpha_z \cos \alpha_y + Y_N \sin \alpha_z - Z_N \cos \alpha_z \sin \alpha_y \\
Y_{XRCF} &= X_N \sin \alpha_z \cos \alpha_y - Y_N \cos \alpha_z - Z_N \sin \alpha_z \sin \alpha_y \\
Z_{XRCF} &= -X_N \sin \alpha_y - Z_N \cos \alpha_y
\end{align*} \quad (91)$$

Note that for zero pitch and yaw,

$$\begin{align*}
X_N &= (X_{XRCF} - XH) \\
Y_N &= -Y_{XRCF} \\
Z_N &= -Z_{XRCF}
\end{align*} \quad (92)$$

reflecting the fact that the mirror is installed upside down at the XRCF.

So in particular if the focal point $P_N(F) = (-f, 0, 0)$ then

$$P_{XRCF}(F) = (XH - f \cos \alpha_z \cos \alpha_y, -f \sin \alpha_z \cos \alpha_y, f \sin \alpha_y) \quad (93)$$
For some reason the Ball SER approximates this as

$$P_X(F) \sim (-f \cos \sqrt{(\alpha_x^2 + \alpha_y^2)}, f \sin \alpha_x, f \sin \alpha_y)$$

which is OK for small $\alpha_y, \alpha_z$.

The XSS is at HRMA nodal coordinates

$$
\begin{pmatrix}
X_N(XSS) \\
Y_N(XSS) \\
Z_N(XSS)
\end{pmatrix} =
\begin{pmatrix}
+LS \cos \alpha_z \cos \alpha_y \\
+LS \sin \alpha_z \\
-LS \cos \alpha_z \sin \alpha_y
\end{pmatrix}
$$

11.3 HXDS Motion

The HXDS stage moves in XRCF X, Y and Z. For a tilted mirror, one must convert from XRCF X, Y and Z to MNC X, Y and Z to obtain the STF to MNC translation-rotation matrix.

11.4 FAM Motion

Treatment of the FAM is complicated by the fact that the FAM axes are inverted with respect to the mirror axes.

The FAM rotates and translates the origin of STF coords, $O_{STF}$, relative to the facility optical axis, $O_{XRCF}$. The three translational axes of the FAM define a (moving) FAM coordinate system with origin at $O_{STF}$. Move the FAM to the FOA so that the STF and FC origins coincide; then the FAM coordinate system is coincident with a (fixed) DFC (Default FAM Coordinate) system which is almost aligned with the XRCF axes. We record the transformation from DFC to XRCF axes as:

$$P(XRCF) = R(DFC,XRCF)P(DFC)$$

where the matrix is a misalignment matrix close to unity. Let the FAM position readouts at $O_{XRCF}$ be $F_0$. Now move the FAM to an arbitrary position with FAM readouts $F$. Then the DFC coordinates of the STF origin are

$$O_{STF}(DFC) = F - F_0$$

and the DFC coordinates of a position with FAM coords $P(\text{FAM})$ are

$$P(DFC) = O_{STF}(DFC) + R(DFC, \text{FAM})P(\text{FAM}).$$

Now the instrument is mounted on the LASSZ (a simulator for the SIM translation table). Let the LASSZ reading be $L$, and the LASSZ reading when $O_{STT} = O_{STF}$ be $L_0$. The sign of LASSZ is such that $L$ increases with XRCF $+Z$, FAM $+Z$, or SC $-Z$, STF $-Z$. A point with LSI coordinates $P(LSI)$ has FAM coordinates

$$P(\text{FAM}) = -P(LSI) - O_{LSI}(STT) + L - L_0$$
So from this we can go from $P(\text{LSI})$ to $P(\text{FAM})$ and hence $P(\text{XRCF})$.

Let's consider a FAM move with the HRMA held constant. At the start, the beam is at chip coords CX0, CY0, and the focal plane coordinates of CX0, CY0 are the central values FX0, FY0. Move the FAM to larger $Y,Z$ FAM readouts. The FAM moves to larger $+Y, +Z$ in XRCF coordinates; the beam will then move to smaller chip coords CX, CY (the detector moved up and to the right, so the beam, which stays put, lands nearer to the lower left of the detector). Of course the beam’s FP coords remain the same. The FP coords of the old chip position CX0, CY0 have moved to larger values of FX0, FY0 (in the default XRCF focal plane system with signs $-1,-1$).

The pixlib routine pix_setup_mirror gets its arguments in FAM coordinates. The mirror angles are also chosen wrt XRCF signs. Specifically, FAM angles of all zero result in an STF to DFC transformation which inverts STF relative to DFC.

The HXDS stage axis misalignment is from a 1996 Dec 27 memo of Ian Evans.

<table>
<thead>
<tr>
<th>Table 31: Assumed Misalignments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stage</td>
</tr>
<tr>
<td>HXDS</td>
</tr>
<tr>
<td>FAM</td>
</tr>
</tbody>
</table>

11.5 FAM Motion, old copy

The FAM data file returns relative XRCF coordinates which we will designate as $P_{\text{FAM}}(\text{XRCF}) = X_{\text{FAM}}, Y_{\text{FAM}}, Z_{\text{FAM}}$ and absolute XRCF orientations $\theta_x, \theta_y, \theta_z$. We need to convert this to an STF-MNC translation-rotation matrix. Let us assume we have converted the FAM variables to units of mm and radians. Then from Part 1 of this memo, we need to find the parameters of

$$P(\text{MNC}) = O_{\text{STF}}(\text{MNC}) + R(\text{STF, MNC})P(\text{STF}).$$

(96)

These are

$$O_{\text{STF}}(\text{MNC}) = R(\text{XRCF, MNC})(O_{\text{STF}}(\text{XRCF}) - O_{\text{MNC}}(\text{XRCF}))$$

(97)

and

$$R(\text{STF, MNC}) = R(\text{XRCF, MNC})R(\text{FAM, XRCF})R(\text{STF, SIC})$$

(98)

(The earlier versions of this memo used a misalignment matrix to allow for FAM axis misalignment with the XRCF. In the present version it is assumed that this misalignment has been taken out by Ball in the data coming from the FAM).

Now

$$O_{\text{STF}}(\text{XRCF}) = O_{\text{FAM}}(\text{XRCF}) + dO_{\text{FAM}}(\text{XRCF}) + P_{\text{FAM}}(\text{XRCF})$$

(99)

where $O_{\text{FAM}}$ is the XRCF focus at XRCF coordinates (XH-f,0,0) and $dO$ is the offset of the FAM coordinate origin relative to that point. The trouble is that we don’t reliably know $dO_{\text{FAM}}$ and it
can change every time the FAM is switched off and on. It must be derived from measurements of the beam centroid. The FAM rotation matrix is

\[ R(FAM, XRCF) = \text{Rot}(3\pi/2, \theta_z, \pi/2)\text{Rot}(\theta_y, \theta_z, 0) \]  \quad (100)

12 AXAF Spacecraft

In this section I describe the geometry of the AXAF spacecraft and other coordinate systems used in the project.

- The primary positional reference is the HRMA Central Aperture Plate (CAP) reference point, which I will designate \( H1 \). This is the origin of AXAF Project HRMA coordinates. It is offset from our data analysis reference point, the nominal optical node \( H0 \). \( H1 \) is a physical datum which can be surveyed, while \( H0 \) is a theoretical point which must be modelled. It is the nominal ‘thin lens’ position from which we measure off-axis angles at the focal plane - it’s where the photons ‘appear to come from’. If this were exactly true, we’d have a constant plate scale, but actually the effective nodal point depends both on energy and off-axis angle. Nevertheless, we can adopt a conventional nodal point and make astrometric position corrections as a function of position and energy, relative to the positions derived using that conventional nodal point.

- Another reference point is \( G1 \), the origin of project OTG coordinates. The analogous data analysis reference point is \( G0 \), the nominal grating node.

- Reference point \( X1 \) marks the origin of Spacecraft Coordinates, a fictitious point out in space beyond the SIM.

- Reference point \( F \) is the flight focal position.

- \( A0 \), the center of the aperture in the spacecraft-to-IUS interface plane.

- \( A1 \), the center of the aperture at the front edge of the paraboloids (which is the origin of the ray trace system).

12.1 Project coordinate systems

12.1.1 Spacecraft coordinates (SC-1.0)

The Spacecraft (Observatory) coordinate system \( X_A, Y_A, Z_A \) (SC/TS ICD 4 Nov 1992, 3.2.1.1.1) is as follows: [?],[?] The X axis is parallel to the HRMA centerline; the aperture is toward positive X, while the SIM is at lower values of X. The Y and Z axes are in the plane of the SIM, such that
the ACIS radiator is toward positive Z and the Y axes completes an X, Y, Z right handed set. The coordinates are also called SCX, SCY, SCZ when we want to refer to a spacecraft coordinate system in general rather than AXAF in particular. \((X_A, Y_A, Z_A)\) are measured in 'inches', which is a unit of length defined to be exactly 0.02540m. The center of the aperture in the AXAF/IUS interface plane is defined to have coordinates \((500, 0, 0)\). The spacecraft trunnion plane has SCZ=14. The coordinates of the HRMA nodal point \(H0\) in SC coordinates are \((X_A(H0), 0, 0)\) where the value of \(X_A(H0)\) is 428.116. The focus is at \((31.836, 0.0, 0.0)\).

12.1.2 HRMA coordinates (HRMA-2.0)

The project has defined Cartesian coordinates \((X_H, Y_H, Z_H)\) fixed in the HRMA cap midplane, which are called **HRMA coordinates**. The origin of HRMA coordinates \(H1\) is at the HRMA CAP reference point. The HRMA \(X_H\) axis is along the HRMA optical axis, and positive X is toward the entrance aperture. Units of HRMA coordinates shall be mm.

The Spacecraft and HRMA coordinate systems are the fundamental ones for hardware alignment, but for data analysis of observations it’s easier to use the HRMA nodal point \(H0\) as origin. This point is calculated to be offset by 18.15 mm from the HRMA CAP datum A. The HRMA mirror nodal coordinate (MNC) system is \((X_N, Y_N, Z_N)\), where

\[
\begin{pmatrix}
  X_N \\
  Y_N \\
  Z_N \\
\end{pmatrix} = \begin{pmatrix}
  X_H - X_H(H0) \\
  Y_H \\
  Z_H \\
\end{pmatrix}
\]

The finite conjugate focus is at HRMA nodal coordinates \((-10256.0, 0.0, 0.0)\). (IF1-20 Obs/SI ICD). Note that

\[
\begin{pmatrix}
  X_N \\
  Y_N \\
  Z_N \\
\end{pmatrix} = \begin{pmatrix}
  (SCX - SCX(H0)) \ast 25.4 \\
  SCY \ast 25.4 \\
  SCZ \ast 25.4 \\
\end{pmatrix}
\]

where SCX(H0) (or \(X_A(H0)\)) is +428.116.

In the following table are listed reference points for various parts of the spacecraft. For XRCF, I give XRCF coordinates in inches for easy comparison with the drawings, although elsewhere in this document XRCF coordinates are measured in mm. The original interface document gave a different position for the HRMA node from the one currently in use, so these numbers need to be rechecked.

12.2 Project Coordinate Systems

There are a plethora of existing coordinate systems in use describing positions relative to the HRMA mirror. They are used in the assembly and alignment of the hardware but they will not be used in the kind of data analysis I am concentrating on in this memo. They are presented for reference.

12.2.1 Orbiter coordinate system

The Space Shuttle Orbiter coordinate system [?] is used to locate the spacecraft within the Orbiter payload bay during the launch phase. It is measured in inches with the $+X_O$ axis downwards at launch (i.e. toward orbiter aft end), the $+Y_O$ axis to starboard, and the $+Z_O$ axis toward the top side (tail side) of the orbiter (i.e. upwards at landing). During launch, the origin of spacecraft coordinates is at orbiter coordinates

$$\begin{pmatrix} X_O \\ Y_O \\ Z_O \end{pmatrix} = \begin{pmatrix} 596.0 \\ 0.0 \\ 400.0 \end{pmatrix}$$  \hspace{1cm} (103)

The relation between Orbiter and Spacecraft coordinates is

$$\begin{pmatrix} X_A \\ Y_A \\ Z_A \end{pmatrix} = \begin{pmatrix} X_O - 596.0 \\ Y_O \\ Z_O - 400.0 \end{pmatrix}$$  \hspace{1cm} (104)

12.2.2 Payload coordinate system

The Space Shuttle payload coordinate system [?] is fixed with respect to the payload, probably. It is measured in inches. In the stowed position, payload and Orbiter coordinates are parallel, and related by

$$\begin{pmatrix} X_P \\ Y_P \\ Z_P \end{pmatrix} = \begin{pmatrix} X_O - 596.0 \\ Y_O \\ Z_O - 200.0 \end{pmatrix} = \begin{pmatrix} X_A \\ Y_A \\ Z_A + 200.0 \end{pmatrix}$$  \hspace{1cm} (105)
12.2.3 The Telescope Ensemble Coordinate System

The document EQ7-002 Rev D, [?] describing the HRMA, defines the Telescope Ensemble Coordinate System \((X_T, Y_T, Z_T)\) with somewhat different axis choice (+Z is the optical axis) and with origin at the focus. Presumably this is the on-orbit, zero-g focus \(f_0\), but the document doesn't say. The document IF1-20 OBS/SI ICD [?] defines the Telescope Coordinate System \((X_T, Y_T, Z_T)\) to be identical with spacecraft coordinates.

12.2.4 Optical Bench Assembly System

The OBA system [?] is

\[
\begin{pmatrix}
X_{OBA} \\ Y_{OBA} \\ Z_{OBA}
\end{pmatrix} = \begin{pmatrix}
X_{FP} - 28.5 \\ Y_{FP} \\ Z_{FP}
\end{pmatrix} = \begin{pmatrix}
X_A - 60.336 \\ Y_A \\ Z_A
\end{pmatrix}
\]  

(TRW AXAF I system alignment plan). I won't discuss it further.

12.2.5 OTG Coordinates (OTG-2.0)

The OTG coordinates system \((X_G, Y_G, Z_G)\) has \(X_G\) parallel to \(X_H\) and \(Y_G, Z_G\) parallel to \(Y_A, Z_A\). \(X_G = 0\) is the side of the OTG closest to the focal plane. This system (AXAF-OTG-2.0) is offset by 2.50 in (63.5mm) relative to the Grating Nodal system (AXAF-OTG-1.0) of interest for data analysis.

The HETG dispersion direction is rotated 5 deg counterclockwise from \(Y_A\) viewed from \(X_A = 0\). METG is rotated the same amount clockwise. The inner and outer radii of the OTG are 234.95 and 558.80 mm.

12.2.6 Project FPSI Coordinate System

The Focal Plane Science Instruments coordinate system \((X_F, Y_F, Z_F)\) is essentially identical to the LSI system defined in this document. However, the SE30 [?] definition specifies the origin as the 'desired aim point', while my LSI definition specifically selects a single nominal aim point for each instrument.

12.2.7 SIM and ISIM coordinates

ISIM coordinates are defined in the OBS/SI ICD [?] with their origin at spacecraft coordinates (31.836, 0.0, 0.0) near the focus (and thus defined only while the spacecraft is assembled); SIM coordinates are defined in the System Alignment Plan D17388, with their origin at the SIM/OBA
interface. Both are usually measured in inches. I recommend use of the more generally defined data analysis coordinate systems FP (fixed wrt the HRMA) and STF (fixed wrt the SIM) defined below. SIM and OBA coordinates are identical after assembly.

\[
(X_{SIM}, Y_{SIM}, Z_{SIM}) = (X_A, Y_A, Z_A) - \begin{pmatrix} 31.836 \\ 0 \\ 0 \end{pmatrix}
\]

and

\[
(X_{SIM}, Y_{SIM}, Z_{SIM}) = (X_A, Y_A, Z_A) - \begin{pmatrix} 60.336 \\ 0 \\ 0 \end{pmatrix}
\]

12.2.8 SAOSAC coordinates (HRMA-3.1)

The SAOSAC coordinate system \((X_{OSAC}, Y_{OSAC}, Z_{OSAC})\) is slightly different again. In the SAOSAC system, at XRCF, the Z-axis increases towards the SI along the FOA, while the X and Y axes are in the aperture plane with the +Y axis vertical. The origin of SAOSAC coordinates is at CAP Datum A, which has nodal X-coordinate \(X_N(DatumA) = 18.15\).

\[
\begin{pmatrix} X_{OSAC} \\ Y_{OSAC} \\ Z_{OSAC} \end{pmatrix} = \begin{pmatrix} Y_N \\ -Z_N \\ X_N(A) - X_N \end{pmatrix}
\] (107)

12.2.9 Summary of useful HRMA Cartesian systems

\[
\begin{pmatrix} X_N \\ Y_N \\ Z_N \end{pmatrix} = \begin{pmatrix} X_H - X_H(H0) \\ Y_H \\ Z_H \end{pmatrix} = \begin{pmatrix} X_N(A1) - Z_{OSAC} \\ +X_{OSAC} \\ -Y_{OSAC} \end{pmatrix}
\] (108)

\[
= \begin{pmatrix} (SCX - SCX(H0)) \cdot 25.4 \\ SCY \cdot 25.4 \\ SCZ \cdot 25.4 \end{pmatrix}
\]
